

Pangram checker – Explanation of solution.

To solve the task I created a function. Parameter of this function is our input (the phrase we want to check). Script compares this input with a constant English alphabet. If there is a letter, that is present in alphabet, but missing in input – script saves this letter in another constant `missingLetters`. If this constant is empty after check, it means that all letters of English alphabet have been found and our input is a pangram. If there is at least one letter in the constant `missingLetters`, it means that input isn't a pangram and script shows all missing letters.
